Motivation
In medical terminologies, new releases introduce new concepts, remove obsolete concepts and reorganize others through remapping. Managing change in large terminologies can be burdensome to users.

Status Web Services
Status web services have been developed to help manage change in three major medical terminologies, whose use is required for the Meaningful Use certification criteria: RxNorm, SNOMED CT and LOINC. While the RxNorm service has been part of the RxNorm API for several years, we developed equivalent services for SNOMED CT (including concepts specific to the U.S. extension of SNOMED CT) and LOINC more recently, for the purpose of validating value sets for clinical quality measures.

The information returned by the service depends on the information available in the underlying terminology.

The RxNorm API status¹ returns:
- Status – active, “alien” (i.e., present in one of the source terminologies, but without an RxNorm type), remapped, retired or unknown.
- Last active release date
- Concept information for active and remapped status.

The SNOMED CT Status web service² returns:
- Current status – retired, active or moved
- Effective time – the version of the latest change
- SNOMED CT identifiers for remapped concepts

The LOINC mapto API³ returns an array of LOINC identifiers when the original identifier is remapped.

All three web service APIs are available in two flavors, SOAP-based and RESTful. Each API also has a version function so that users can determine which version of the data set is being used. The services are updated as new terminology versions become available.

Use Cases
Use cases for these status web services include:
- Supporting information retrieval systems that accept concept identifiers as queries (e.g., MedlinePlusConnect uses this service)
- Determining outdated or remapped drug concepts in clinical drug databases (e.g., updating value sets)

Our terminology status web services typically receive an average of 469,000 calls per month.
